

GLA02 Records: Release 33

Level-1A atmospheric data (GLA02) include the normalized relative backscatter for the 532 nm and 1064 nm channels, and low-level instrument corrections such as laser energy normalization for both channels, background subtraction, range-square correction, dead-time correction for 532 nm, photon coincidence for 532 nm, and detector-gain correction for 1064 nm. Vertical profiles for both channels are shown in the following diagrams:

The vertical resolution, calculated from each return bin's width, is 76.8 m. GLA02 consists of 1 sec records with the time and position information corresponding to the first shot (of 40) of that second. Linear interpolation between seconds should be used to obtain location and time information for each of the 40 Hz profiles within a second.

Note that the height of the top bin within each layer is not constant. The height above the ellipsoid at which GLAS acquires lidar data depends on the height of the local topography below the nadir

point of the satellite. GLAS is designed to acquire lidar data such that the end of the profile, or the last bin of the lowest layer, is always roughly 1.5 km below the geoid. Keeping this profile over changing topography causes the height of the top bin, and all subsequent bins of the profile, to change too. This "vertical shifting" only occurs on second boundaries. Within a second, all 40 shots are acquired starting at the same height. To determine the height of the top bin, examine the "i_Rng2PCProf" variable (byte offset 28476) for the 532 nm channel and "i_rng2CDProf" variable (byte offset 29500) for the 1064 nm channel. Subtracting these values from the height of the spacecraft, "i_Hsat" (byte offset 56636) yields the height above the geoid for the top bin.

See the [GLAS Atmosphere Data Dictionary](#) for details of each record, including units and scaling factors. The GLAS science team created this dictionary. Units and scaling factors with a "d" indicate double-precision constants; for example, a value of "1.0d5" is equivalent to 100,000. The variable "pe/bin" represents photo electrons per bin.

The following codes denote data types throughout the remainder of this document.

i1b: 1-byte integer
i2b: 2-byte (short) integer
i4b: 4-byte (long) integer
r4b: 4-byte real
r8b: 8-byte real

Values in parentheses indicate the record size, for example:

i2b(39): 39 records of 2-byte integers
i1b(48,40): 48-record x 40-record array of 1-byte integers

Nearly all integers are signed. Exceptions are noted in the following record table.
